RPL功能模块

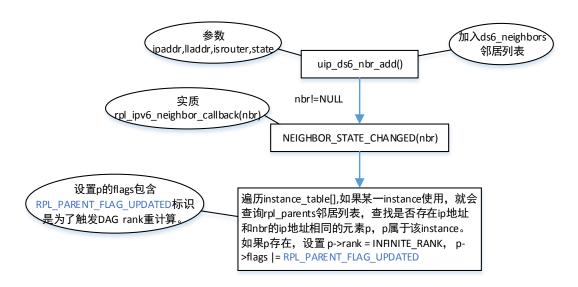

RPL DODAG Building Process

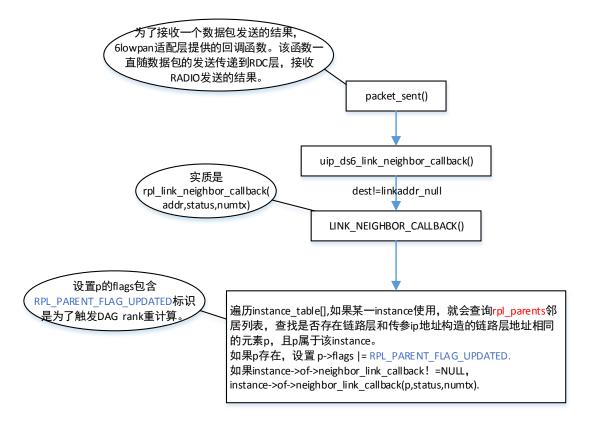

RPL 形成下行路由

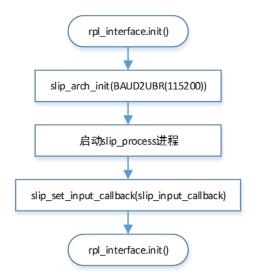

注: uip_ds6_nbr_rm()也会执行NEIGHBOR_STATE_CHANGED(nbr),即满足条件也会触发DAG rank重计算。

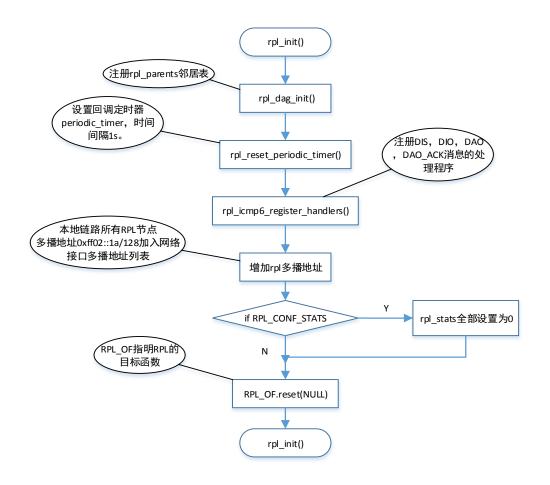

处理DAO消息,检测到环,设置 p->rank = INFINITE_RANK, p->flags |= RPL_PARENT_FLAG_UPDATED, 也会触发DAG rank重计算。

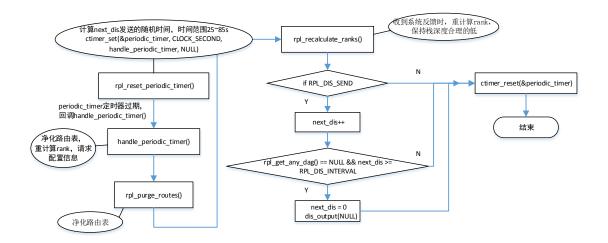

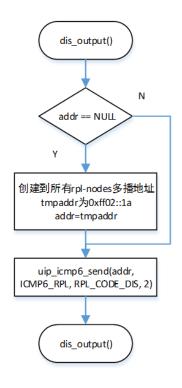

注:linkaddr_null = { { 0, 0, 0, 0, 0, 0, 0, 0 } }

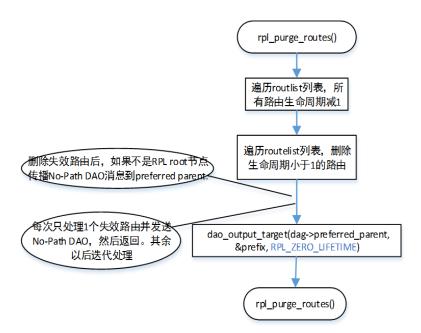

instance->of->neighbor_link_callback()调用rpl_get_nbr(p),为了获得在ds6_neighbors列表中 其链路层地址和rpl_parents列表中的p的链路层地址相同的邻居,即p对应的邻居nbr。更新 该邻居的link metric,设为计算后的新的ETX。

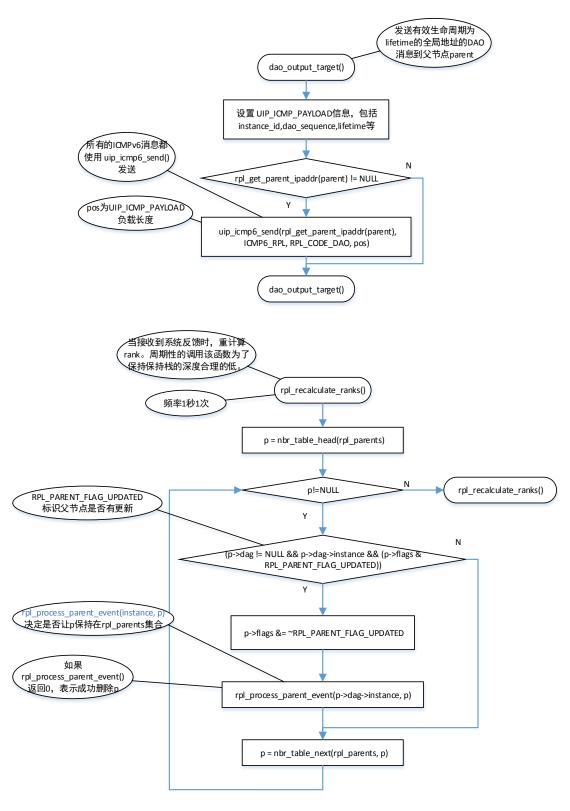

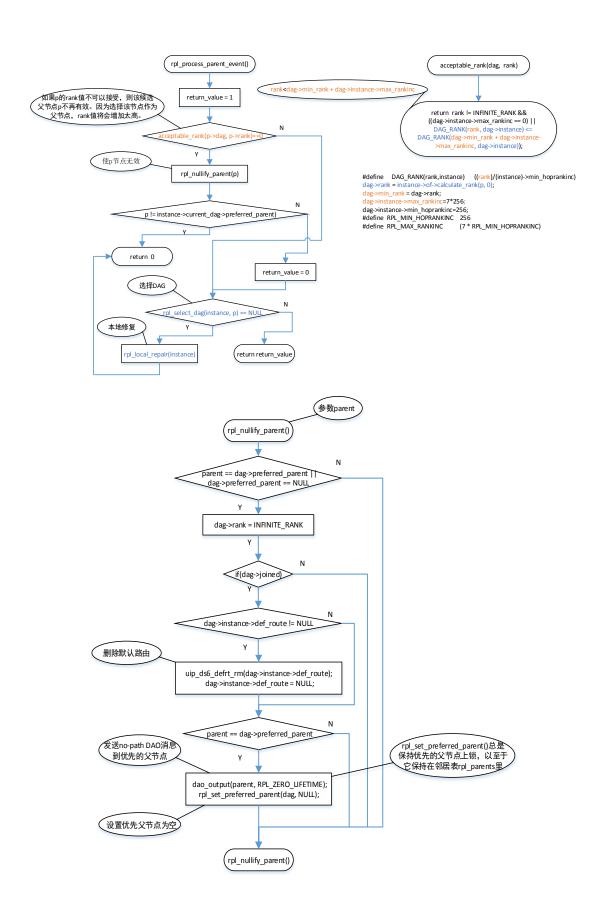

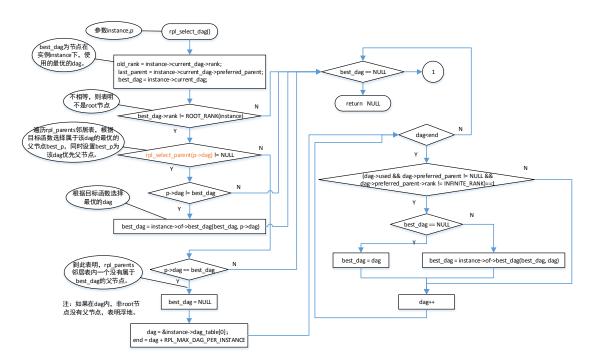

注:如果定义了RPL多播,多播路由列表mcast_route_list的路由有效期减一,并且删除多播路由列表mcast_route_list中的失效路由。但是默认未使能多播engine.

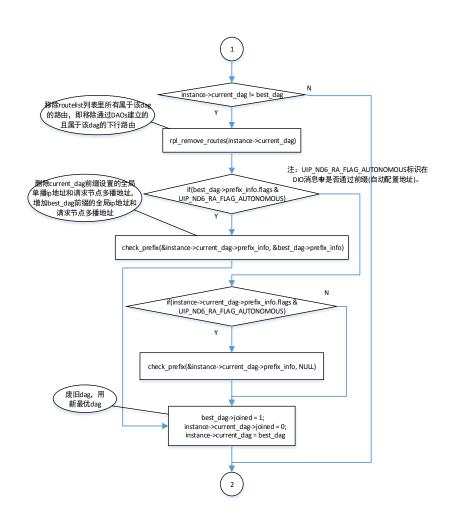

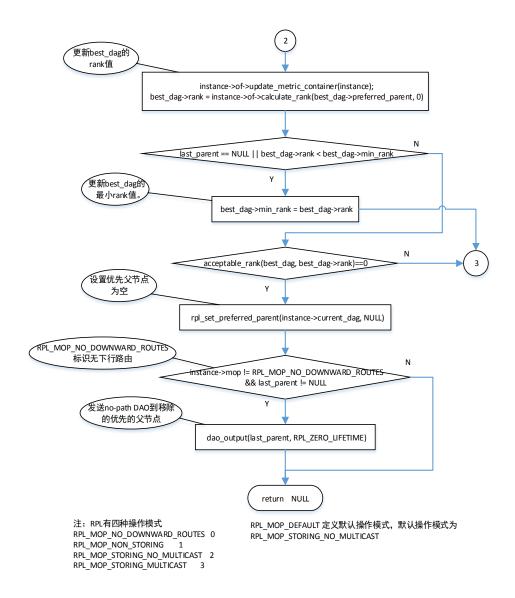

注:重计算父节点rank且标识该父节点有更新时,或DIO发送者作为候选父节点成功加入rpl_parents邻居表时,调用rpl_process_parent_event(instance,p)。

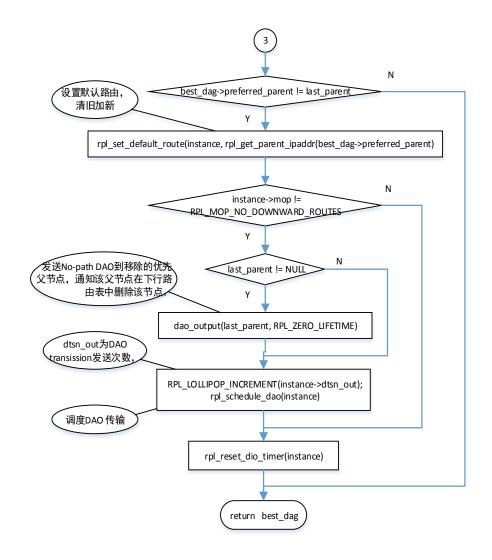

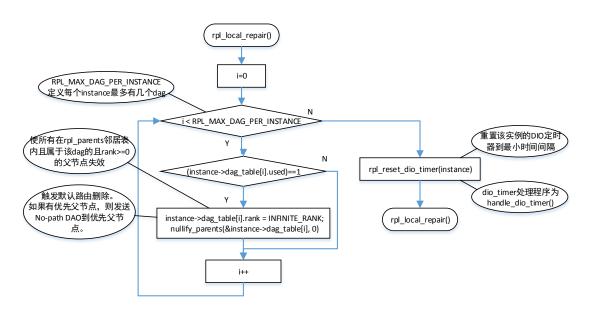

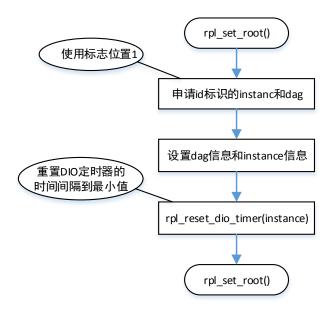

注:非root节点可以加入多个DAG,但是只选择每个实例instance中最好的一个DAG即best_dag使用,同时instance->current_dag-best_dag。 发送DIO消息时,通告的dag也是instance->current_dag。 注:非root节点的best_dag是目前在实例instance下使用的best_dag和p->dag中最优的。但是呢,如果p->dag=best_dag且best_dag浮地,best_dag就是该实例instance下dag表中最优的dag。

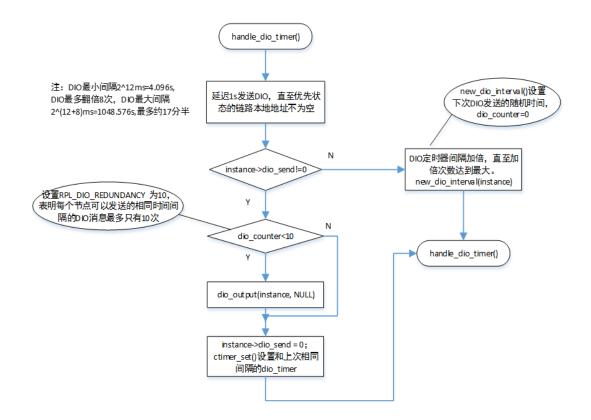

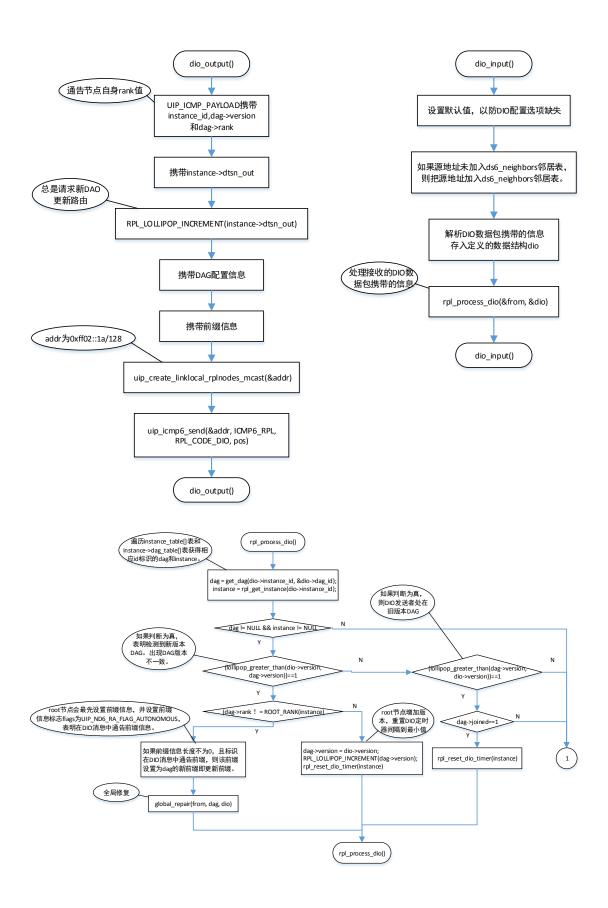

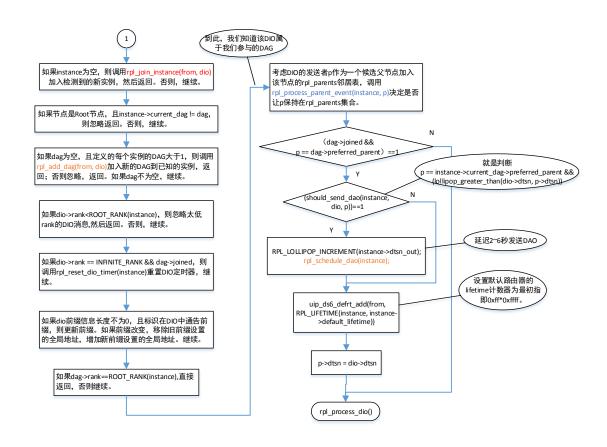

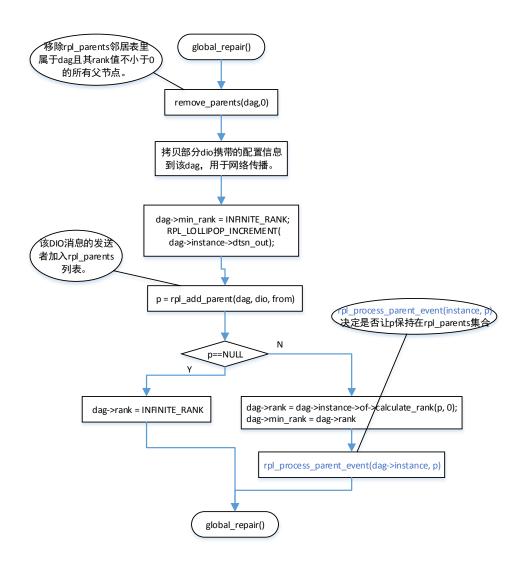

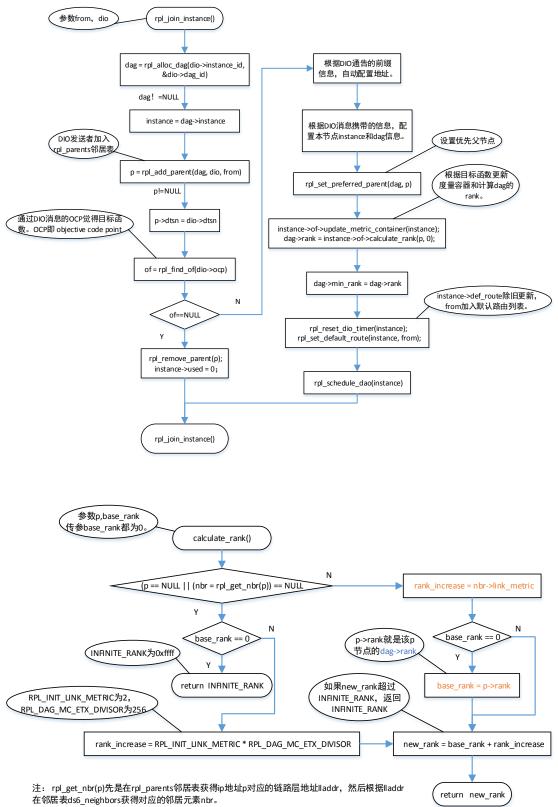

注:设置dag信息包括version=240, joined=1, grounded=0, preference=0, rank=ROOT_RANK(instance)为256. 设置instance信息包括操作模式默认为存储无多播,目标函数MRHOF, max_rankinc=7*256,min_hoprankinc=256,dio_intdoubl=8,dio_intmin=12, default_lifetime=0xff,lifetime_unit=0xffff,current_dag=dag等。

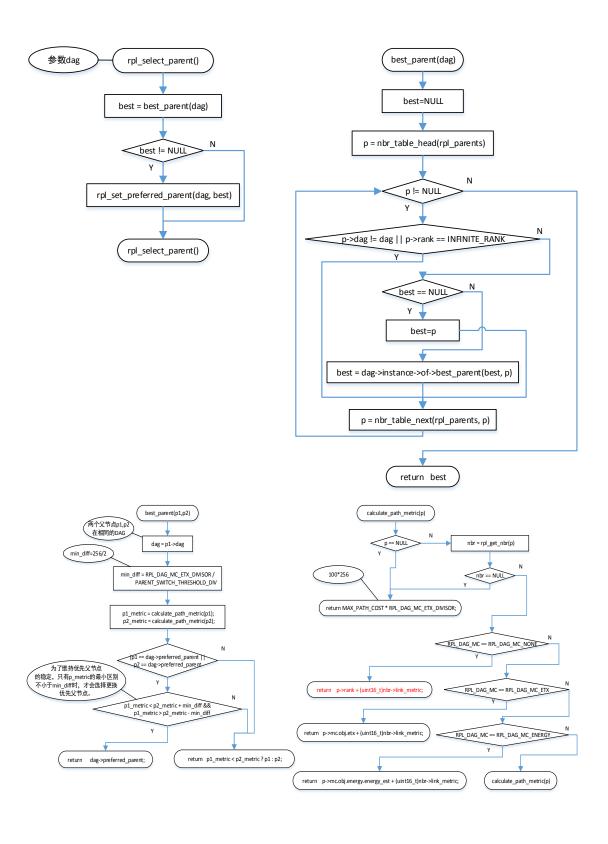

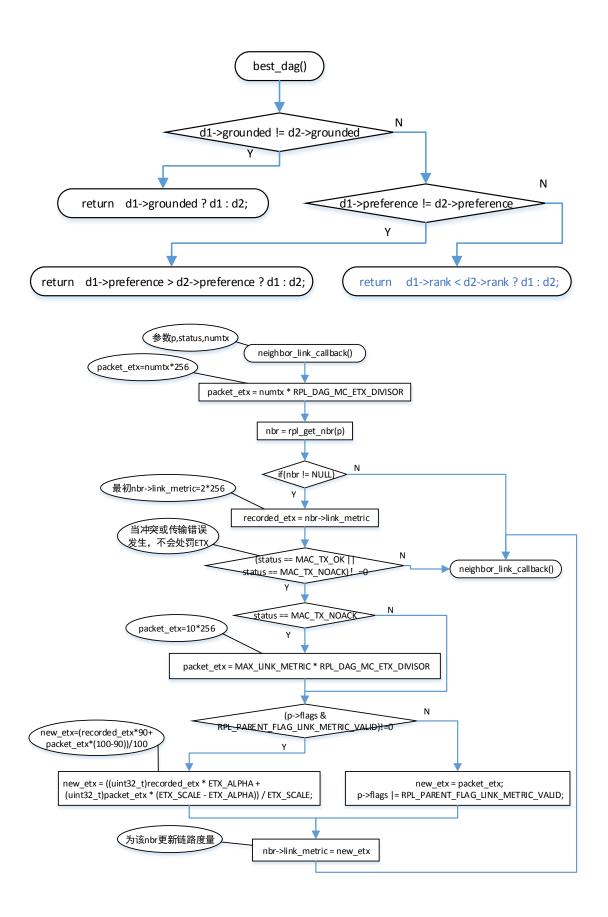

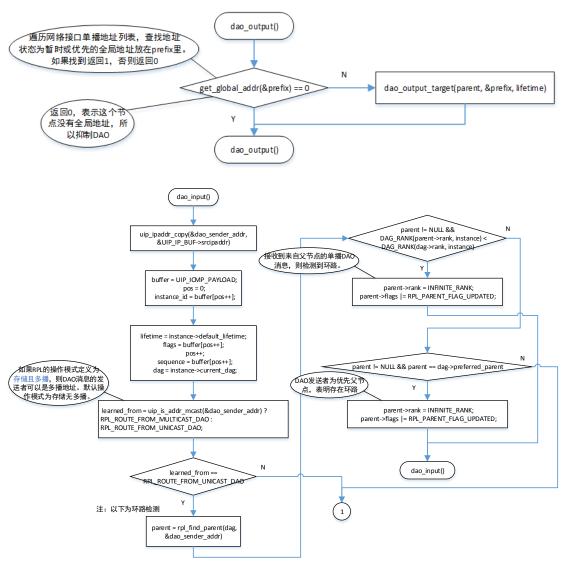

节点p成功加入邻居表rpl_parents的前提是其在邻居表ds6_neighbors有相应的链路层地址lladdr。然后根据lladdr在邻居表ds6_neighbors获得对应的邻居元素nbr,接着设置该nbr最初的link_metric。nbr->link_metric = RPL_INIT_LINK_METRIC * RPL_DAG_MC_ETX_DIVISOR。

注:单播DAO消息都是上行数据流,子节点向优先父节点发送的消息。
